

ELLEN
MACARTHUR
FOUNDATION

BPA COMMENTS ON THEIR MAY 2019 REPORT

The scientists who developed plastics have been working for more than 40 years to upgrade plastic products so that they remain fit for purpose but will become biodegradable if discarded at the end of their useful life, and will then be recycled back into nature by bacteria and fungi much more quickly than ordinary plastic. Their efforts have resulted in a technology which has become known as oxo-biodegradable (or oxo-bio) plastic. This is essentially environmental insurance, which automatically removes unwanted plastic if it becomes litter.

One would expect organisations such as the Ellen MacArthur Foundation (EMF), ostensibly dedicated to protecting the environment, to want to work with the oxo-biodegradable plastics industry and other suitably qualified experts, to understand the technology and to campaign for it to be used as an alternative to ordinary plastic. They should be asking themselves “is oxo-bio plastic better for the environment than ordinary plastic?” Instead they published a report by a non-scientist, with no prior consultation with the experts in the industry who have been using the technology for decades.

They know that ordinary plastic is the source of most of the microplastics in the environment, and yet they seek to blame oxo-biodegradable technology for this, citing no evidence that any microplastics ever found in the environment are oxo-biodegradable.

They know that ordinary plastic will lie or float around for decades, and that oxo-biodegradable plastic will do so in a relatively short timescale. They know that conditions in the environment are variable and yet they demand accurate prediction of the timescale for biodegradation under any and all conditions.

They know that ordinary plastic will not fully biodegrade for very many decades, and yet they question the ability of oxo-biodegradable plastic to fully biodegrade.

They know that in all these respects oxo-biodegradable technology will provide an environmental benefit as compared with ordinary plastic, and yet they call for it to be banned. Why?

If EMF succeed in their lobbying against oxo-biodegradable plastic, they will have deprived the world of the only means available to prevent the plastic waste which has escaped into the open environment from accumulating there for many decades.

No special conditions are necessary for oxo-biodegradable technology to work. The only conditions necessary are oxygen and bacteria, both of which are ubiquitous in the open environment. Elevated levels of light and heat will accelerate the process still further, but they are not necessary.

Some stakeholders are still being influenced against oxo-biodegradable plastic by the EMF report of November 2017 on what EMF call “oxo-degradable” plastic.

EMF say that “This report was originally published on 6 November 2017. In June 2018 the report was temporarily removed whilst the Foundation investigated queries raised by a third party.” The third party was Symphony Environmental, who had engaged lawyers to point out to EMF that their report was inaccurate and misleading.

Symphony had a meeting with EMF, and discovered that the author of the report is not a scientist, and that he had misunderstood the papers which he has cited – see below. It is notable that in their report they say *“we do not assume any liability whatsoever for the accuracy and completeness of such information.”*

EMF avoided a court action by publishing a revised report with a fundamental difference. The 2017 report said that oxo-bio plastic simply fragmented, but they admitted in their May 2019 report that oxo-degradable” plastics **are manufactured so that they can degrade faster than conventional plastics and that they do become biodegradable, although it is not yet possible accurately to predict the duration of the biodegradation for such plastics.**

In their 2019 report (which for some reason has become known as “the oxo statement”) EMF say “Oxo-degradable plastics are being produced and sold in many countries, with society being led to believe that they completely biodegrade in the environment within relatively short timescales.” It seems that EMF do not understand the difference between oxo-degradable and oxo-biodegradable plastics.¹ In fact, oxo-degradable plastics are ordinary plastics, which degrade abiotically, but do not biodegrade in the environment at all – except over a very long period of time.

By contrast, it is perfectly reasonable to lead society to believe that oxo-biodegradable plastics “completely biodegrade in the environment within relatively short timescales.” See below.

EMF continue that “compelling evidence suggests that oxo-degradable plastics take longer than claimed to degrade.” This is a meaningless statement, because nobody makes degradation claims in respect of oxo-degradable plastic.

If EMF are referring to oxo-biodegradable plastic, they do not say who is making the claims, and what timescale is being claimed. It is possible to produce oxo-biodegradable plastic products so that degradation starts immediately after manufacture, but they would have no useful life. Therefore, nobody is claiming that they will degrade instantly, but it can certainly be claimed that they will degrade and biodegrade very much more quickly than ordinary plastic anywhere in the open environment. Indeed, the length of the useful life of the plastic product can be programmed by adjusting the formulation of the oxo-biodegradable masterbatch. This cannot be done with plastics marketed as “compostable.”

MICROPLASTICS

EMF continue that “they fragment into small pieces which contribute to microplastics pollution.” Nobody doubts that this is true of oxo-degradable (i.e. ordinary) plastic, and this is why ordinary plastic should not be used for short-life products unless upgraded with oxo-biodegradable technology.

¹ “Oxo-degradation” is defined by CEN (the European Standards authority) in TR15351 as “degradation resulting from oxidative cleavage of macromolecules.” This describes ordinary plastics, which abiotically degrade by oxidation in the open environment and create microplastics, but do not become biodegradable except over a very long period of time.

By contrast, “oxo-biodegradation is defined by CEN as “degradation resulting from oxidative and cell-mediated phenomena, either simultaneously or successively”. This means that the plastic degrades by oxidation until its molecular weight is low enough to be accessible to bacteria and fungi, who then recycle it back into nature.

However, as mentioned above, EMF admit that oxo-biodegradable plastics do become biodegradable, so the only remaining issues are rate and extent.

Some of the microplastics found in the environment are coming from tyres and man-made fibres - and recycling is also a source of microplastics.²

However, most of the microplastics found in the environment are caused by the well-known fragmentation of ordinary plastic when exposed to sunlight. These fragments are very persistent because their molecular weight is too high for microbes to consume them, and can remain so for decades.

This is why oxo-biodegradable plastic was invented. The plastic falls apart because the molecular chains have been dismantled and it is no longer a plastic. (When EMF asked Professor Jakubowicz for his advice he made this point³, but they omitted it from their report).

The “precautionary principle” is often relied upon by EMF, who seem to think that it means “ban first and ask questions later.” It was described by Lord Sumption on 31st December 2021⁴ as “essentially a principle for making decisions radically affecting people’s lives without adequate evidence.” Lord Sumption is one of the United Kingdom’s most distinguished jurists.

The view of the European Court of Justice⁵ is that “...if it is not to adopt arbitrary measures, which cannot in any circumstances be rendered legitimate by the precautionary principle, the competent public authority must ensure that any measures that it takes, even preventive measures, are based on *as thorough a scientific risk assessment as possible.*”

In Europe “as thorough a scientific risk assessment as possible” would be made by the European Chemicals Agency, who are the European Union’s scientific experts in this field, but EMF do not mention that in 2017 the Agency made a call for evidence on this very subject. They received a large amount of evidence from a wide range of stakeholders (see eg the Evidence from Intertek⁶) and informed the BPA on 30th October 2018 that they are not convinced that it creates microplastics. ECHA has never produced a dossier justifying any restriction on oxo-biodegradable plastic.

Notwithstanding this, EMF still urge stakeholders to believe that “oxo-degradable plastics should be banned until further detailed research is carried out on their behaviour in real world environments.”

As to “further detailed research on their behaviour in real world environments” and “as thorough a scientific risk assessment as possible” Oxomar was an interdisciplinary study sponsored by the French government.⁷

² <https://www.sciencedirect.com/science/article/pii/S2772416623000803>

³ He said “OBD plastics only fragment within a few years ... This assertion is not correct. The degradation process is not only a fragmentation but it is an entire change of the material from a high molecular weight polymer to monomeric and oligomeric fragments and from hydrocarbon molecules to oxygen containing molecules which can be bio-assimilated.”

⁴ Daily Telegraph

⁵ in T-13/99 Pfizer Animal Health SA v Council ECLI:EU:T:2002:209

⁶ <https://www.biodeg.org/wp-content/uploads/2021/01/Intertek-Report-to-ECHA-24.5.18.pdf>

⁷ <https://www.biodeg.org/wp-content/uploads/2021/07/Final-report-OXOMAR-10032021.pdf>

The Oxomar scientists reported in March 2021, after four years of research on oxo-biodegradable plastic in the real-world environment, that it does properly biodegrade even in the oceans much more quickly and efficiently than ordinary plastic.

Research at Queen Mary University⁸ was on samples of LDPE and oxo-LDPE which had been surface-weathered in sea water for 82 days, undergoing natural variations in sunlight and UV intensity.

See also the evidence of Dr.Graham Swift, Vice-chairman of the ASTM Technical Committee on Biodegradable Plastics as to the correlation of laboratory studies and the real-world environment.⁹

Although EMF admit in their May 2019 report that “oxo-degradable” plastics are manufactured so that they can degrade faster than conventional plastics and that they do become biodegradable, they still say that “it is not yet possible accurately to predict the duration of the biodegradation for such plastics.”

It never will be possible, because conditions in the open environment are variable, and for that reason a broad indication only can be given as to timescale. It is however possible to say with certainty that at any given time and place in the open environment an oxo-biodegradable plastic item will biodegrade significantly more quickly than an ordinary plastic item. Queen Mary University say (para 2.3) up to 90 times faster.

That is the point - **do we want ordinary plastic which can lie or float around for decades, or oxo-biodegradable plastic which will be recycled back into nature much more quickly?** Of course, we don't want plastic in the sea at all, but that is not the present reality.

PLASTIC LITTER

Plastic is immensely useful and is the best way to prevent food wastage and sickness, by protecting our food from contamination and damage¹⁰ - but there is one fundamental problem – that if it gets into the open environment as litter it will lie or float around for decades, and perhaps 100 years. That is the reason why there is so much opposition to plastic, but it is now possible to solve this problem by redesigning the plastic itself, with oxo-biodegradable technology.

Plastic waste has been identified as a serious environmental problem by many governments around the world, and measures have been proposed for reducing the amount of plastic in use and for redesigning and recycling plastic products. These are laudable aims and we support them, but it is unrealistic to think that these measures are going to prevent all plastic waste getting into the open environment in the foreseeable future, even in the developed world.

La Tribune reported on 7th June 2019 that 600,000 tonnes of plastic are being dumped by 22 countries in the Mediterranean Sea every year, and the situation is even more alarming at global level, with 8 million tonnes ending up in the sea each year.

⁸ <https://www.biodeg.org/wp-content/uploads/2022/10/QM-published-report-11.2.20-1.pdf>

⁹ Evidence to UK Government Oct 2019 <https://www.biodeg.org/wp-content/uploads/2021/02/Swift-evidence-to-BEIS.pdf>

¹⁰ See the Denkstatt Report <https://www.biodeg.org/wp-content/uploads/2019/11/denkstatt-report-v1.pdf>

This plastic will rapidly fragment into microplastics which can lie or float around for many decades, and banning peripheral items like drinking straws, cotton buds, and microplastics in cosmetics, is not going to solve the problem. A substantial amount of plastic will continue to get into the open environment from which it cannot realistically be collected, and it is this fraction of plastic waste for which most governments¹¹ have no answer.

INNOVATION

Oxo-biodegradable plastics are not intended to replace litter control, but to deal with the consequences of *failure* to control litter on land or water. Although plastic litter is usually found on the surface, if it should become buried after a short exposure to sunlight the oxo-biodegradable technology will still work, as (unlike photo-degradable plastic) it is not dependent on constant exposure to sunlight. Oxo-biodegradable plastic is designed to be inert deep in landfill, because biodegradation of anything in anaerobic conditions generates methane.

It is said by EMF that oxo-bio plastic packaging is - by its very design - not meant for long-term reusable applications. This is correct, and indeed obvious. It is meant mainly for packaging which might become litter, and which is not normally reusable or worth recycling. This does not for example include PET bottles, which *are* worth collecting. As to recycling see <https://www.biodeg.org/subjects-of-interest/recycling-2/>

Oxo-biodegradable plastic products are made from ordinary polyethylene or polypropylene. They are made in the same way as normal plastic, but the manufacturer adds a masterbatch which accelerates a change in the molecular structure soon after its useful life has expired so that it ceases to be a plastic. This type of plastic can therefore be made by ordinary plastics factories at little or no extra cost.

It places a much lower burden on scarce resources than crop-based plastic, because it is made from a by-product of refining oil for fuels, most of which would otherwise be wasted. A Life-cycle Assessment by Intertek in May 2012¹² confirmed that oxo-biodegradable plastic had the best LCA, and lowest global-warming potential, of all materials used for making carrier bags and bread bags.

CONFUSION

It is said by EMF that *“Oxo-degradable plastics and similar materials are marketed and referred to in different ways, including oxo-biodegradable, photo/thermo-degradable, oxo-fragmentable or pro-oxidant additive containing plastics - a terminology we believe may confuse consumers, policymakers and companies.”*

Oxo-biodegradable plastics are marketed as oxo-biodegradable, and are not marketed by the other descriptions suggested by EMF.

¹¹ Except the governments of the UAE, Saudi Arabia, and other countries in the Middle East, Africa, and South America, who have mandated the use of oxo-biodegradable technology.

¹² <http://www.biodeg.org/wp-content/uploads/2018/11/intertek-final-report-15.5.121.pdf>

However, EMF themselves create confusion by failing to distinguish between oxo-degradable plastic (which fragments but does not biodegrade except over a very long time) and oxo-biodegradable plastic (which has a different chemical structure and becomes biodegradable much more quickly). See the scientific definition by CEN cited above.

So as to avoid further confusion it should be noted that oxo-biodegradable plastic is not made from food-crops such as corn-starch. Those are hydro-biodegradable plastics (often misleadingly described as “compostable” plastics), which are not a solution to plastic litter, and are unsuitable for everyday use.

We agree that there is a need for clarity, but policymakers and commentators such as EMF are responsible for the confusion. They should stop referring to oxo-biodegradable plastics as “oxo-degradable,” “photo/thermo-degradable,” “oxo-fragmentable,” or “pro-oxidant additive-containing” (PAC) plastics. There is only one accurate description.

EMF say that unless otherwise stated, all references to oxo-degradable plastics are deemed to refer to oxo-degradable and oxo-biodegradable plastics. This is misleading because, as already noted, these two types of plastic have fundamentally different characteristics and cannot be treated alike. They cite (but then forget) the CEN definition of oxo-biodegradation mentioned above, as *“degradation resulting from oxidative and cell-mediated phenomena, either simultaneously or successively.”*

The distinction between degradation (the abiotic phase) and biodegradation (the biotic phase) is crucial. These two steps involving first the oxidation and breakdown of the polymer, and then the consumption of the oxidized residues by microorganisms, occur continuously during the process of degradation/biodegradation.

EMF cause further confusion by including a discussion of compostable plastics in a report on oxo-bio plastic, when it is well-known that oxo-bio plastics are not marketed for composting, and are not designed to comply with the standards for compostable plastics such as EN13432 and ASTM D6400. Further confusion is caused by including enzymatic plastics, as these are neither oxo-degradable nor oxo-biodegradable.

However, as EMF have mentioned plastic marketed as compostable, they should have pointed out that it (a) does not properly biodegrade in the open environment and thus contributes to microplastic pollution in the environment, (b) is not compostable – because it converts into CO₂ gas, not into compost, (c) negatively affects the recycling of conventional plastic, as it cannot be recycled in a post-consumer waste stream and (d) fails to deliver a proven environmental benefit.¹³

As to oxo-biodegradable plastics, it is said that there are *“claims that such plastics, when they end up in land or aquatic environments, degrade into harmless residues within a period ranging from a few months to several years.”*

¹³ <https://www.biodeg.org/subjects-of-interest/composting/>

These claims are correct, and the difference in timescale results from the formulation of the plastic product (some are designed to degrade faster than others) and from the fact that the conditions in the environment where they are lying or floating are variable from place to place and from time to time.

It is said by EMF that *fragmentation should then accelerate the process of biodegradation i.e. the breakdown triggered by microorganisms into naturally-occurring molecules such as carbon dioxide and water, but the speed of this biodegradation process depends on multiple criteria. These criteria include the fragment size, the quantity of additives, and the environmental conditions to which the material is subjected.* This is nearly correct, but it is not fragmentation into small pieces which makes the material available to micro-organisms, it is the reduction of the molecular weight of the material itself. Also, the rate of degradation does not depend primarily on the *quantity* of additives, but the balance within the masterbatch between prodegradants and stabilisers.

According to EMF *“During this time evidence suggests that fragments from oxo-degradable plastics contribute to microplastic pollution and this poses an environmental risk, particularly in the ocean.”* In fact, as mentioned above, after a call for evidence and studying oxo-bio technology for ten months the European Chemicals Agency informed the BPA on 30th October 2018 that they were not convinced that microplastics are formed, and they have never produced a dossier to support any restriction of oxo-biodegradable plastic. As to the marine environment see the Oxomar report.

What EMF do not mention is that ordinary plastic is a much more significant source of microplastics which are very persistent, and that in that respect oxo-biodegradable plastic is much better for the environment

EMF say that they expect oxo-biodegradable plastic to degrade and biodegrade *“over a time-scale short enough for particles not to accumulate in ecosystems.”* Clearly oxo-biodegradable plastic products cannot be designed to degrade instantly, for they would have no useful life, but they are designed to degrade and biodegrade much more quickly than conventional plastics so that there is a much shorter dwell-time for any particles to accumulate in eco-systems. In fact, if oxo-bio plastics had been brought into use even 20 years ago the enormous ocean garbage patches would not have accumulated, and most of the plastic would have biodegraded and returned to nature.

Neither EMF nor any government has ever defined what they mean by “a reasonable timescale” but they know that oxo-bio plastic takes a much shorter time than ordinary plastic. It is well known that ordinary plastic fragments do not become biodegradable for many decades.

EMF say that they are not sure that oxo-bio plastic will fully biodegrade, but they give no reasons why, once biodegradation has commenced, it should not continue until it is complete. In fact, tests have been done by Eurofins laboratories showing biodegradation of 88.9%, and by Intertek showing 92.74% (only 90% is required by EN13432 or ASTM D6400 for plastic marketed as compostable). Also, testing has been done by Prof. Jakubowicz in Sweden showing 91%.

Standard tests will never find 100% carbon-evolution because some of the material converts into water and biomass. **Even if it did not fully biodegrade it would still be better than ordinary plastic, which would have created persistent microplastics but would not have biodegraded at all.**

EMF create further confusion in fn 5 when they say “the US Federal Trade Commission (FTC), has issued Revised Green Guides (2012), Claim 260.8: “it is deceptive to *misrepresent*, directly or by implication, that a product or package is degradable, biodegradable, oxo-degradable, oxo-biodegradable, or photodegradable.” This does not prevent a claim of oxo-biodegradability provided that the claim is substantiated, and qualified by appropriate wording.

There is a further misleading statement in fn 5 where EMF say “FTC Staff Warns Plastic Waste Bag Marketers That Their “Oxodegradable” Claims May Be Deceptive.” This related only to garbage sacks, and was concerned with a marketing claim. The technology is not designed to degrade in anaerobic conditions in landfill and the FTC advised the marketers to make this clear.

WHAT IS OXO-BIODEGRADABLE PLASTIC NOT FOR?

1. It is NOT a disposal route. The intention is that the plastic is reused, recycled, and disposed of like normal plastic, but the d2w technology will make sure that if the plastic gets into the open environment the molecular weight will reduce very rapidly so that it becomes biodegradable.
2. It is NOT for Landfill. If the plastic has been taken to landfill, it has been responsibly disposed of and there is no need for it to degrade. Also if anything biodegrades in anaerobic conditions it will generate methane, which is undesirable unless the landfill has been designed to collect the gas. Oxo-biodegradable plastic will not degrade in the absence of oxygen.
3. It is NOT for Composting. See <https://www.biodeg.org/subjects-of-interest/composting/> Six short points on the type of plastic marketed as “compostable”:
 - (a) Does not deal with the problem of plastic litter in the environment, because it is designed and tested to biodegrade in a composting facility.
 - (b) Does not convert into compost (EN13432 and ASTM D6400 require it to convert into CO₂ gas)
 - (c) Is designed for a deliberate linear process and is not circular. The material is intended to be wasted and lost to atmosphere by conversion into CO₂ in a composting facility.
 - (d) Cannot be re-used, recycled, or made from recycle.
 - (e) Leaves microplastics in the compost and in the open environment. On 2nd December 2022 the UK Environment Minister said: “Compostable plastics must be treated in industrial composting facilities to be broken down and, when processed incorrectly, can be a source of microplastics¹⁴ and contaminate recycling streams.
 - (f) Is not wanted by many industrial composters and local authorities. On 14th November 2022 the UK Environment Minister said “our call for evidence suggests these materials are often stripped out at the start of the process and landfilled or incinerated.” “This packaging does not contribute to a circular economy in the same way as packaging that can be reused or recycled into new packaging or products do, as compostable plastic packaging is generally intended to be used only once.”

¹⁴ See also <https://www.chemeurope.com/en/news/1176729/>

It should not therefore be described as compostable or biodegradable. It should not be encouraged, and should instead be banned.

THE SCIENTIFIC EVIDENCE

As mentioned above, the best scientific evidence is the four-year “Oxomar” study, sponsored by the French government, of oxo-biodegradable plastic in the real-world environment. The Oxomar scientists reported in March 2021 that oxo-biodegradable plastic does properly biodegrade even in the oceans much more quickly and efficiently than ordinary plastic.

EMF cite a large number of earlier reports, but as a general point, we have found that reports and literature-reviews by researchers who are not experts in oxo-biodegradable technology show a lack of understanding of the mechanism by which oxo-biodegradable plastics acquire biodegradability, and the function of the stabilisation package.

This lack of understanding leads to testing in conditions, and according to standards, inappropriate for oxo-biodegradable plastics. For example, failure to run the TIER 1 test in ASTM D6954; or failure to run that test until the TE[%] < 5% or Mw < 5000 Da; or testing under anaerobic conditions, or failure to understand that the product contains stabilisers which delay the onset of degradation, or failure to understand that the product is not intended for composting. This means that their reports on oxo-biodegradation often causes unnecessary confusion and are of little value.

A case in point is the 2015 Michigan State University Report by Selke et al on which a BPA member-company commented at the time.¹⁵

Another case in point is the 2007 Chico report. The author does not mention the source of “oxo-degradable LDPE” used in the tests, while other materials are clearly described and the source specified. It is not therefore known which OBP masterbatch was used, in which concentration, and with which stabilization package. One cannot therefore know the timescale for which it was designed, nor even be sure that it was oxo-biodegradable plastic at all. In addition, the Chico report makes the statement: “LDPE with additive is not biodegradable as it does not meet the requirements of ASTM D-6400”. This standard is irrelevant, as D6400 is a standard for biodegradation in the special conditions found in industrial composting, and not for biodegradability in the open environment for which oxo-bio plastic is designed. They ought to have known that the appropriate standard for OBP is ASTM D6954.

The material studied by Chico was not abiotically degraded, as required by Tier 1 of D-6954 as a first, critical step, and it is not therefore surprising that subsequent attempts to measure biodegradation according to ASTM D-5338 showed little result. Further, testing the material in anaerobic conditions shows a fundamental misunderstanding of the technology, as it is axiomatic that oxygen is required. Finally, the Chico experiments cannot have been properly designed and/or performed, as even the Kraft paper control, PLA lids, sugar cane lids, corn starch trash bags, and Ecoflex bags showed no degradation after 60 days. In short this is a very amateurish report.

¹⁵ <http://www.biodeg.org/MSU%20Reponse%2024.4.15.pdf>

The 2015 UNEP report¹⁶ does not show that oxo-degradable plastics simply fragment into small pieces including microplastics. Indeed it admits that they may be utilised by micro-organisms, but questions the rate and extent (to which we have referred above). Further, this report is not based on original experimental work and the author is a geologist rather than a polymer scientist. The micro-particles of plastics found in the oceans were from ordinary plastics.

Another case in point is the recent experiments at Plymouth University¹⁷ by marine biologists. If the researchers had been polymer scientists they would have understood that an oxo-biodegradable shopping bag contains stabilisers to give the product a useful service life and which would have delayed the onset of abiotic degradation of the bag. Simply to say that it had not degraded after two years is meaningless.

The researchers at Plymouth should also have understood that oxo-biodegradable bags are intended to degrade if they become litter in the open environment on land or sea with an abundance of oxygen and usually exposed to sunlight, and that the experiment they performed was not therefore a representative test. This is because they had submerged it in a dark environment under a pontoon. Polyethylene and polypropylene, have a specific gravity less than 1, so they would normally float on the surface.

EMF say that *“oxo-degradable plastics left in the open environment, in the UK, degrade to small fragments in two to five years, and they will still remain visible as litter before they start to fragment.”* What they do not say is that they convert into biodegradable material which is no longer a plastic, and that ordinary plastic would degrade to small fragments in a similar timescale but would persist for very much longer before they biodegrade.

The biodegradability of oxo-biodegradable polymers has been extensively studied and reviewed in scientific articles for more than 40 years. (See e.g. Scott, “Degradable Polymers, Principles and Applications” (ISBN 1-4020-0790-6) and Scott, “Polymers and the Environment” (ISBN 10: 0-85404-578-3). Also Ammala et al., 2011; Koutny et al., 2006a; Albertsson and Karlsson, 1980; Chiellini et al., 2006; Jakubowicz et al., 2006; Ojeda et al., 2011; Albertsson et al., 1987; Bonhomme et al., 2003; Corti et al., 2010; Jakubowicz et al., 2011).

According to Gewert et al¹⁸ “Abiotic degradation produces carbonyl groups that increase the hydrophilicity of the polymer and thus increase its availability for biodegradation”.

Dussud et al¹⁹ compared three polyethylene-based polymers, with similar surface roughness, and observed increase in oxidation and hydrophilicity brought about by the inclusion of a prodegradant additive and then by oxidative degradation, which is a clear factor in the ability of organisms to colonize the material.

¹⁶ For BPA comment see <https://www.symphonyenvironmental.com/resource/opa-comment-on-unesp-report/>

¹⁷ For BPA comment see <https://www.biodeg.org/wp-content/uploads/2019/11/opa-comments-on-plymouth-10.pdf>

¹⁸ Environ. Sci.: Processes Impacts, 2015, 17, 1513

¹⁹ Frontiers in Microbiology 1 July 2018 Vol. 9,1571

During these experiments, the degree of colonisation (cell count) is not only an indication of the ability of microorganisms to physically populate the surface of the material, but is also influenced by each material's ability to act as a source of nutrients for the microorganisms.

Eyheraguibel et al²⁰ identified the products of degradation facilitated by a prodegradant additive in an OBP, as oxidised oligomers. The characterisation of the oligomers, before and after exposure to the bacterial strain *R. rhodochorus*, provides insight into the oligomeric products of polyolefin degradation and their biodegradability. The paper demonstrates that after sufficient molecular-weight reduction, the oligomers are soluble in water and undergo near-total biodegradation: 60% biodegradation after only four days, 95% after 240 days.

Arraez et al²¹ say "The design of materials with the ability to degrade once their service life has finished is one of the industrial approaches to face the problems of accumulation of plastic wastes in the environment. The purpose of such process is to generate chemical changes in the polymer structure as a result of oxidation in air. This is achieved by using special additives called pro-oxidant/pro-degradants (oxo additives) consisting of organic salts of metals "

"The degradation process induced by the incorporation of oxo additives in polymers is called oxo-biodegradation and is defined as the process of transforming complex molecules into simpler elements from oxidation reactions that promote the cleavage of the chemical bonds, the incorporation of polar groups, and the reduction in molecular weight in polymer chains favouring their interaction with microorganisms in the environment, transforming them into bio-assimilable materials. Microorganisms such as bacteria fungi and algae use the oxidation products of the polymer chains as carbon sources resulting in the formation of carbon dioxide, water, and biomass."

In August 2019 Queen Mary University London published a report²² the main findings of which were that:

- Oxo-Biodegradable plastic demonstrated up to 90 times more biodegradation than conventional plastic, when aged for the same period of time.
- The degraded material was biodegraded by bacteria found in soil and marine environments.
- Molecular-weight reduction is a critical factor in the rate and extent of biodegradation, showing that biodegradability increases as molecular-weight reduces.
- The use of a prodegradant catalyst such as that in a d2w masterbatch, caused a rapid reduction of molecular-weight.
- The plastic samples tested for biodegradation were abiotically degraded under both real life and laboratory conditions.

²² <https://www.symphonyenvironmental.com/resource/queen-mary-university-london-publishes-positive-study-on-biodegradable-plastic/>

A review of the scientific evidence²³ has been made by Peter Susman KC, a former Deputy Judge of the High Court in England. He found that:

- oxo-biodegradable plastic does facilitate the ultimate biodegradation of plastics in air or seawater by bacteria, fungi or algae, within a reasonable time, so as to cause the plastic to cease to exist as such, far sooner than ordinary plastics, without causing any toxicity;
- that “the benefit is obvious of reducing future contributions to the scourge of plastic pollution of land and sea”;
- that oxo-biodegradable technology is compatible with recycling.

EMF often cite European Bioplastics, SPI Bioplastics Council, European Plastics Converters, Biodegradable Products Institute, and Sustainable Packaging Coalition as authorities, without making clear, contrary to FTC Claim 260.6(e) Example 2, that these are trade organisations supporting commercial products in competition with oxo-biodegradable plastic. By contrast, EMF did not cite any of the peer reviewed scientific publications published in 2017 and 2018 considered by Peter Susman KC.

In particular they fail to cite the evidence from Professor Ignacy Jakubowicz,²⁴ which EMF had themselves requested, that “*The degradation process is not only a fragmentation, but is an entire change of the material from a high molecular weight polymer, to monomeric and oligomeric fragments, and from hydrocarbon molecules to oxygen-containing molecules which can be bioassimilated.*” They are then recycled back into nature by the naturally-occurring micro-organisms. This point is absolutely crucial to an understanding of OBP.

The evidence to the UK Government by Dr. Graham Swift, Vice-chairman of the ASTM Technical Committee on Biodegradable Plastics²⁵ is that *Oxo-biodegradable plastics have been known and used commercially for over half a century. They were developed by the scientists who had developed conventional plastics, who found a way to render ordinary plastic susceptible to controlled oxidative degradation, by using catalysis to produce simple hydrophilic compounds, many known and recognized as biodegradable in widely disparate aerobic environments.*”

He continued “*I do not consider that persistent plastic fragments and smaller, microplastics would be left behind which could have any harmful effect on the open environment, and in particular marine life.*”

Dr. Swift is one of the authors of ASTM D6954. He says “*Of course, conditions in the open environment are variable but there is no need for a standard for each of these conditions. Provided that oxygen is present, a plastic complying with ASTM D6954 will become biodegradable much more quickly than ordinary plastic, and that is its purpose.*”

<http://www.biodeg.org/Reply%20to%20Ellen%20MacArthur%20Foundation%20from%20Prof%20Ignacy%20Jakubowicz%20-%202021-8-17.pdf>

²⁵ Evidence to UK Government Oct 2019 <https://www.biodeg.org/wp-content/uploads/2021/02/Swift-evidence-to-BEIS.pdf>

Oxygen is ubiquitous, and most of the plastic litter is found lying or floating around with abundant access to oxygen, but it is possible to imagine a piece of plastic in anaerobic conditions where abiotic degradation cannot proceed. However if this is in a landfill it does not matter, because the plastic has already been properly disposed of.

It is also possible for a piece of oxo-biodegradable plastic to find itself in anaerobic conditions outside a landfill but this would be very unusual and does not invalidate the general proposition. It is for example possible for plastic to be deprived of oxygen by being heavily bio-fouled in the ocean or buried in sediment, but this is unlikely to happen quickly enough to prevent sufficient exposure to oxygen for abiotic degradation. If it did, then that small proportion of the global burden of plastic litter would perform in the same way as ordinary plastic – no better and no worse.”

LABORATORY TESTING

EN13432 and ASTM D6400 for “compostable” plastic requires biodegradation to be tested in a laboratory (not in a compost heap) but it is suggested that oxo-biodegradable plastic should be tested in outdoor conditions. (para. 49 of Summary) See however the statement of Dr. Graham Swift at that *“It has been my experience that results from laboratory testing are very likely to be reproduced in the real world. I can see no cause for concern that they would not, and have seen no evidence that they have not.”*

Further, in the Oxomar project the scientists stated that “The goal was to evaluate the biodegradation of OXO-bio *in marine waters.*” In their conclusion they reported that “We have obtained congruent results from our multidisciplinary approach that clearly shows that oxo-biodegradable plastics biodegrade in seawater and do so with a significantly higher efficiency than conventional plastics. The oxidation level obtained due to the d2w prodegradant catalyst was found to be of crucial importance in the degradation process.”

As also mentioned above, the report from Queen Mary University London by Rose et. al 11th February 2020. para 2.6 says “prior to testing, samples of LDPE and oxo-LDPE were *surface-weathered in sea water for 82 days*, undergoing natural variations in sunlight and UV intensity.”

CLAIMS

It is alleged by EMF that some claims made by companies in the biodegradable plastics industries are misleading. These allegations are not specified so it is not possible to verify this statement, but misleading claims are sometimes made in every industry. Misleading claims are sometimes made about motor cars, but the way to deal with that is to ban the misleading claims, not the cars.

OTHER ARGUMENTS

There are a number of make-weight arguments in the EMF Report – for example that biodegradable plastic will encourage littering. EMF do not make this argument against crop-based biodegradable plastic, and in any event it is mere speculation. In the opinion of Peter Susman KC “the criticism alleging that oxo-biodegradable plastic technology would materially encourage littering [can only be regarded] as fanciful and unrealistic.”

There is no need to affix a label saying that the product is biodegradable, because it is intended to be used and disposed of in the same way as normal plastic. But even if there were such a label would the kind of person who throws plastic litter out of a car window look first at the label to satisfy himself that it is biodegradable? Suppose however for the sake of argument that they are right and that there would be perhaps 10% more plastic litter - is it better to litter 110 oxo-bio items that will have biodegraded within a few months or even a few years, or 100 ordinary plastic items that will persist for a century or more?

Degradable plastic products (both oxo and hydro biodegradable) have been available to the public for more than 20 years but there is no evidence that people dispose more carelessly of them. In our view it is not acceptable to continue advancing this speculative proposition any longer, while thousands of tons of conventional plastic are getting into the environment every day, which will pollute the environment for decades into the future.

EMF claim that oxo-bio is incompatible with a circular economy, but the opposite is true. Ordinary plastic and oxo-biodegradable plastic can certainly be recycled if collected, but what of the plastic on land or sea which cannot be collected? If that plastic were oxo-bio it would complete the circle by being recycled back into nature by bacteria and fungi.

It is said that oxo-bio products go against two core principles of the circular economy: designing out waste and pollution; and keeping products and materials in high-value use. However, Oxo-biodegradable plastic products can be redesigned, and they are not intended to be wasted – unlike the type of plastic marketed as “compostable” which is intended to be wasted by being converted into CO₂ in a composting facility, and is not kept in high-value use.²⁶

OBP can be reused and recycled during its useful life, and is designed to biodegrade only if it has not been collected for re-use and recycling, but has instead escaped into the open environment as litter.

RECYCLING

It is claimed that *“oxo-degradable plastics negatively affect the quality and economic value of plastic recyclates.”*

As to this, see <https://www.biodeg.org/subjects-of-interest/recycling-2/>

Five short points on recycling:

- Recyclers have to assess the level of degradation of any plastic sent for recycling whether it is oxo-biodegradable or not. They cannot recycle ordinary plastic which has started to degrade after exposure to sunlight.
- If the recyclate is to be used to make short-life products (eg food packaging) it does not matter whether it contains oxo-biodegradable plastic, because biodegradation is actually desirable.
- Stabilisation is necessary only for long-life products, and the producer of long-life products would stabilise them in the same way whether the recyclate contains oxo-biodegradable plastic or not. Normal stabilisation would neutralise any oxo-biodegradable residue, and it is not necessary to know the proportion of oxo-biodegradable plastic (if any) in the feedstock.

²⁶ <https://www.biodeg.org/subjects-of-interest/composting/>

- It is not necessary to separate oxo-biodegradable PE or PP from conventional PE or PP before recycling, but if so desired oxo-biodegradable masterbatch could be made visible to automatic sorting equipment by including a marker.
- Oxo-biodegradable masterbatch is used in PE and PP, but NOT in PET.

Is recycling preferable to biodegradation? Yes in principle, but it is not possible to recycle plastic which has escaped into the open environment from which it cannot realistically be collected. **The ONLY way to deal with it is biodegradation.**

There is a fallacy in footnote 15 of the 2019 Ellen MacArthur Report, that “both the heat and UV ageing tests were performed on samples that were ‘recycled’ (blown into film and then re-pelletised) in-house from primary materials rather than from recovered post-consumer waste material. Therefore, this does not demonstrate the effects of any oxidation as a result of UV ageing that has occurred during use, and/or between disposal and being recycled as in real world environments.”

The fallacy is that if oxidation has occurred in *any* plastic it should not be recycled.

In the last four years alone, enough masterbatch has been sold by one BPA member (Symphony) to make 600,000 tonnes of OBP products from polyethylene and polypropylene. We know that OBP products have been successfully recycled for the past 15 years by BPA members and their customers around the world, and in those 15 years we have heard no reports of any difficulty encountered. Our experience is entirely consistent with the specialist reports referred to above, that oxo-bio plastic can be safely recycled, and recyclers have presented no technical evidence and no actual experience, to the contrary.

Even if the points made in relation to recycling were valid, that is no reason to continue to use ordinary plastic, thousands of tons of which are getting into the oceans every day and will not be recycled. There is no doubt that this will create microplastics and will pollute the environment for many decades into the future.

It is time for a much better dialogue between the recyclers and the OBP industry. If we can combine oxo-biodegradable technology with the three R’s of ‘Reduce, Reuse and Recycle’ and add a fourth R – “Remove,” we can all help win the battle against plastic waste - for the lasting benefit of future generations.

EUROPEAN UNION

We were not entirely surprised to see in December 2022 that the homes and hotels of 18 MEPs and officials had been searched by the police, yielding suitcases stuffed with banknotes.

The reason we were not surprised is that we have never been able to understand how it was possible for the European Parliament to impose a ban on “oxo-degradable plastic” (by Art. 5 of the Single-use plastics Directive 2019/904) without any dossier from the European Chemicals Agency (ECHA) showing any justification for any such ban.

The Commission’s draft Directive did not include any ban on oxo-degradable or oxo-biodegradable plastic, but the Parliament proceeded to legislate, and circumvented all the safeguards against arbitrary legislation provided by Arts. 69-73 of REACH. Could it be that there was some improper influence?

To make matters worse, the Commission had actually asked ECHA (under Art 69 of the REACH Regulation) to study whether these products created microplastics. ECHA received

hundreds of pages of evidence but they informed us in October 2018 that they were not convinced that microplastics were formed. They were instructed to terminate the study.

This Directive has been challenged in the European Court in Luxembourg and the case was heard by five judges on 20th March 2023. We await their decision.

Oxo-biodegradable technology is supplied to plastics manufacturers as a masterbatch in pellet form, so that they can upgrade their products with the same machinery and workforce at little or no extra cost. It is a “drop-in” technology.

CONCLUSION

If EMF succeed in their lobbying against oxo-biodegradable plastic, they will have deprived the world of the *only* means available to deal with long-term pollution of the environment by the plastic waste which has not been collected for responsible disposal.

The EMF Report indicates that it is endorsed by a large number of companies and organisations, some of which are aggressively promoting a competing plastic technology, and others are themselves producers of many of the plastic articles which are found as litter in the environment. EMF has been formally requested by lawyers acting for an OPA member to declare the amounts of money which it has received from those companies and organisations, but it has failed to do so.

The UK Charity Commission should investigate whether the Report was published by EMF with the improper motive of assisting a commercial and political campaign against the oxo-biodegradable plastics industry.

The loser here is the environment, because ordinary plastic is still being used to make products which get into the open environment every day, where they will lie or float around for decades. They should urgently be made with oxo-biodegradable technology, so that they will biodegrade much more quickly and will not leave harmful residues.
